

CPU Performance Evaluation: Cycles Per Instruction (CPI)

- Most computers run synchronously utilizing a CPU clock running at a constant clock rate: Or clock frequency: f

where: Clock rate = $1 / \text{clock cycle}$

$$f = 1/C$$

- The CPU clock rate depends on the specific CPU organization (design) and hardware implementation technology (VLSI) used.
- A computer machine (ISA) instruction is comprised of a number of elementary or micro operations which vary in number and complexity depending on the the instruction and the exact CPU organization (Design).
 - A micro operation is an elementary hardware operation that can be performed during one CPU clock cycle.
 - This corresponds to one micro-instruction in microprogrammed CPUs.
 - Examples: register operations: shift, load, clear, increment, ALU operations: add, subtract, etc.

CPI

- Thus: A single machine instruction may take one or more CPU cycles to complete termed as the Cycles Per Instruction (CPI).

$$\text{Instructions Per Cycle} = \text{IPC} = 1/\text{CPI}$$

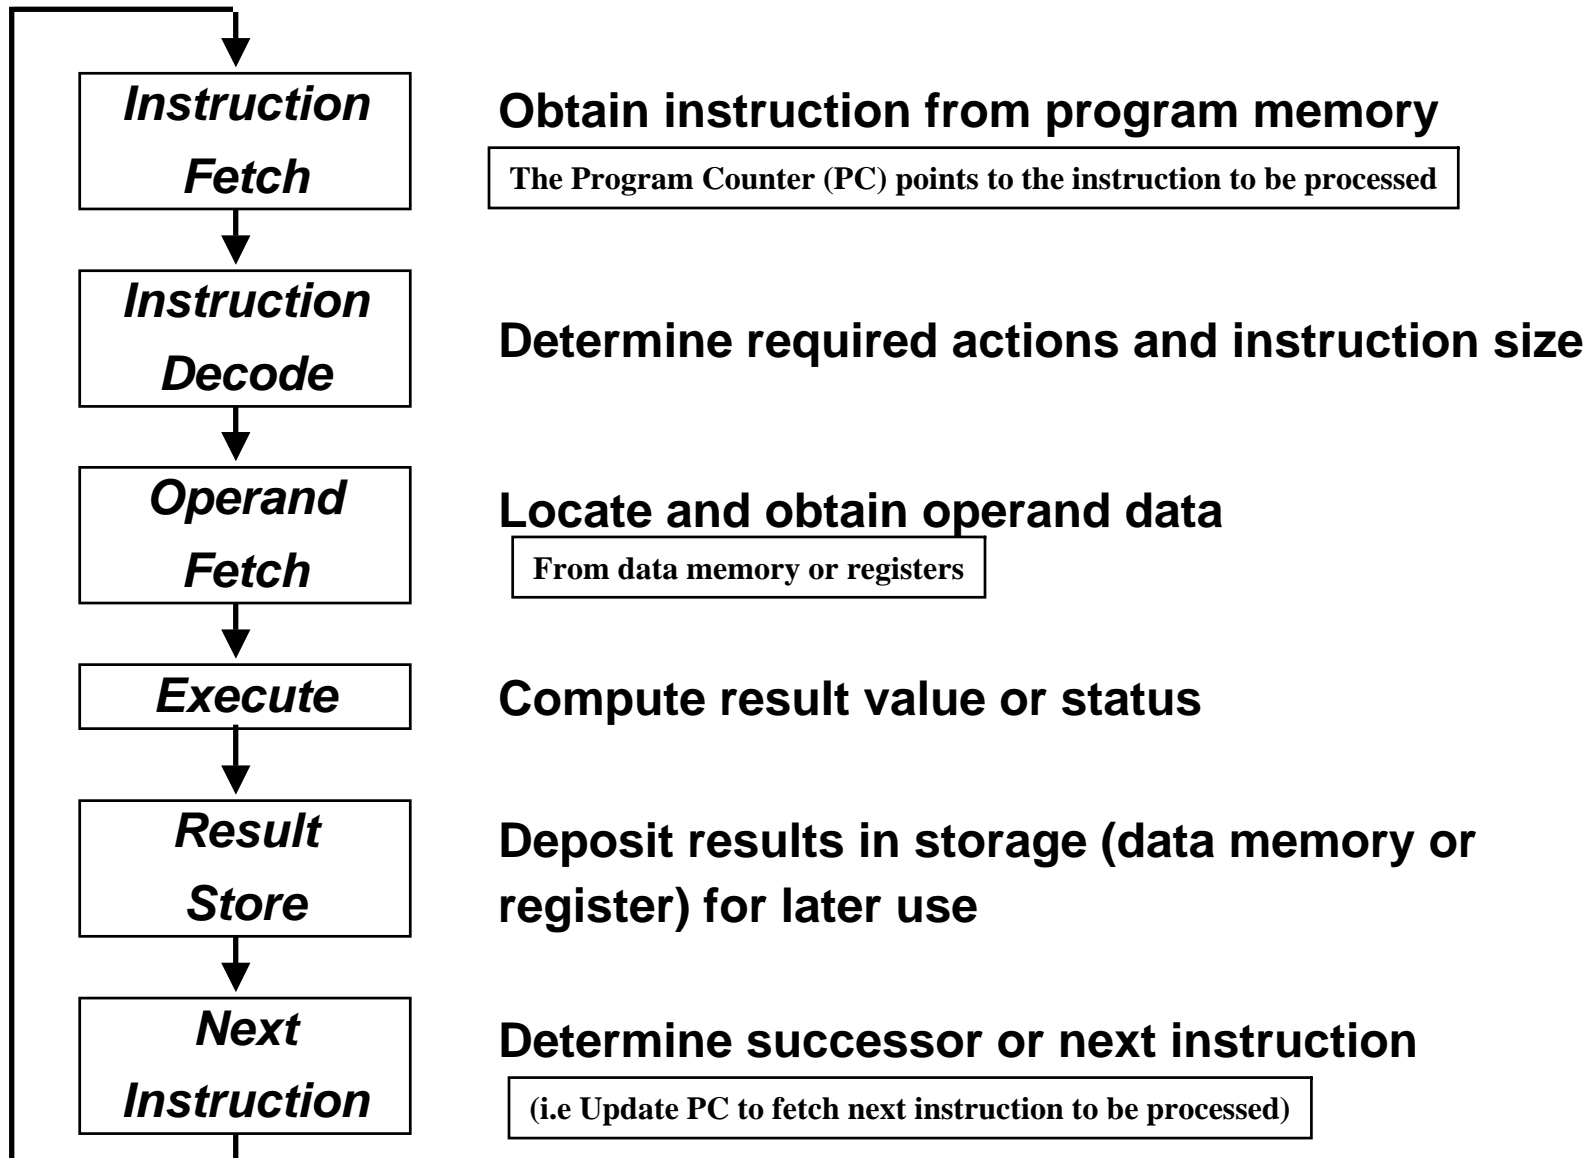

- Average (or effective) CPI of a program: The average CPI of all instructions executed in the program on a given CPU design.

4th Edition: Chapter 1 (1.4, 1.7, 1.8)
3rd Edition: Chapter 4

Cycles/sec = Hertz = Hz
MHz = 10^6 Hz GHz = 10^9 Hz

EECC550 - Shaaban

Generic CPU Machine Instruction Processing Steps

CPI = Cycles per instruction

EECC550 - Shaaban

Computer Performance Measures: Program Execution Time

- For a specific program compiled to run on a specific machine (CPU) “A”, has the following parameters:

- The total executed instruction count of the program. I
- The average number of cycles per instruction (average CPI). CPI
- Clock cycle of machine “A” C Or effective CPI

- How can one measure the performance of this machine (CPU) running this program?

- Intuitively the machine (or CPU) is said to be faster or has better performance running this program if the total execution time is shorter.
- Thus the inverse of the total measured program execution time is a possible performance measure or metric:

$$\text{Performance}_A = 1 / \text{Execution Time}_A$$

Seconds/program

Programs/second

How to compare performance of different machines?

What factors affect performance? How to improve performance?

Comparing Computer Performance Using Execution Time

- To compare the performance of two machines (or CPUs) “A”, “B” running a given specific program:

$$\text{Performance}_A = 1 / \text{Execution Time}_A$$

$$\text{Performance}_B = 1 / \text{Execution Time}_B$$

- Machine A is n times faster than machine B means (or slower? if $n < 1$) :

$$\text{Speedup} = n = \frac{\text{Performance}_A}{\text{Performance}_B} = \frac{\text{Execution Time}_B}{\text{Execution Time}_A}$$

- **Example:** (i.e Speedup is ratio of performance, no units)

For a given program:

Execution time on machine A: Execution_A = 1 second

Execution time on machine B: Execution_B = 10 seconds

$$\begin{aligned} \text{Speedup} &= \text{Performance}_A / \text{Performance}_B = \text{Execution Time}_B / \text{Execution Time}_A \\ &= 10 / 1 = 10 \end{aligned}$$

The performance of machine A is 10 times the performance of machine B when running this program, or: Machine A is said to be 10 times faster than machine B when running this program.

The two CPUs may target different ISAs provided the program is written in a high level language (HLL)

EECC550 - Shaaban

CPU Execution Time: The CPU Equation

- A program is comprised of a number of instructions executed, **I**
 - Measured in: instructions/program AKA Dynamic Executed Instruction Count
- The average instruction executed takes a number of *cycles per instruction (CPI)* to be completed.
 - Measured in: cycles/instruction, **CPI** Or Instructions Per Cycle (IPC):
IPC = 1/CPI
- CPU has a fixed clock cycle time C = 1/clock rate C = 1/f
 - Measured in: seconds/cycle
- CPU execution time is the product of the above three parameters as follows:

$$\text{CPU time} = \frac{\text{Executed Seconds}}{\text{Program}} = \frac{\text{Instructions}}{\text{Program}} \times \frac{\text{Cycles}}{\text{Instruction}} \times \frac{\text{Seconds}}{\text{Cycle}}$$

$$T = I \times CPI \times C$$

execution Time
per program in seconds

Number of
instructions executed

Average CPI for program

CPU Clock Cycle

(This equation is commonly known as the CPU performance equation)

EECC550 - Shaaban

CPU Average CPI/Execution Time

For a given program executed on a given machine (CPU):

$$\text{CPI} = \frac{\text{Total program execution cycles}}{\text{Instructions count Executed (I)}}$$

(i.e average or effective CPI)

$$\rightarrow \text{CPU clock cycles} = \text{Instruction count} \times \text{CPI}$$

$$\begin{aligned} \text{CPU execution time} &= \text{CPU clock cycles} \times \text{Clock cycle} \\ &= \text{Instruction count} \times \text{CPI} \times \text{Clock cycle} \\ \mathbf{T} &= \mathbf{I} \times \mathbf{CPI} \times \mathbf{C} \end{aligned}$$

execution Time
per program in seconds

Number of
instructions executed

Average
or effective
CPI for
program

CPU Clock Cycle

(This equation is commonly known as the CPU performance equation)

CPI = Cycles Per Instruction

EECC550 - Shaaban

CPU Execution Time: Example

- A Program is running on a specific machine (CPU) with the following parameters:
 - Total executed instruction count: 10,000,000 instructions
 - Average CPI for the program: 2.5 cycles/instruction.
 - CPU clock rate: 200 MHz. (clock cycle = $C = 5 \times 10^{-9}$ seconds)
i.e 5 nanoseconds
- What is the execution time for this program:

$$\text{CPU time} = \frac{\text{Seconds}}{\text{Program}} = \frac{\text{Instructions}}{\text{Program}} \times \frac{\text{Cycles}}{\text{Instruction}} \times \frac{\text{Seconds}}{\text{Cycle}}$$

$$\begin{aligned} \text{CPU time} &= \text{Instruction count} \times \text{CPI} \times \text{Clock cycle} \\ &= 10,000,000 \times 2.5 \times 1 / \text{clock rate} \\ &= 10,000,000 \times 2.5 \times 5 \times 10^{-9} \\ &= 0.125 \text{ seconds} \end{aligned}$$

Nanosecond = nsec = ns = 10^{-9} second
MHz = 10^6 Hz

$$T = I \times \text{CPI} \times C$$

EECC550 - Shaaban

Factors Affecting CPU Performance

$$\text{CPU time} = \frac{\text{Seconds}}{\text{Program}} = \frac{\text{Instructions}}{\text{Program}} \times \frac{\text{Cycles}}{\text{Instruction}} \times \frac{\text{Seconds}}{\text{Cycle}}$$

T	=	I	x	^{Average} CPI	x	C
		Instruction Count		Cycles per Instruction		Clock Rate (1/C)
Program						
Compiler						
Instruction Set Architecture (ISA)						
Organization (CPU Design)						
Technology (VLSI)						

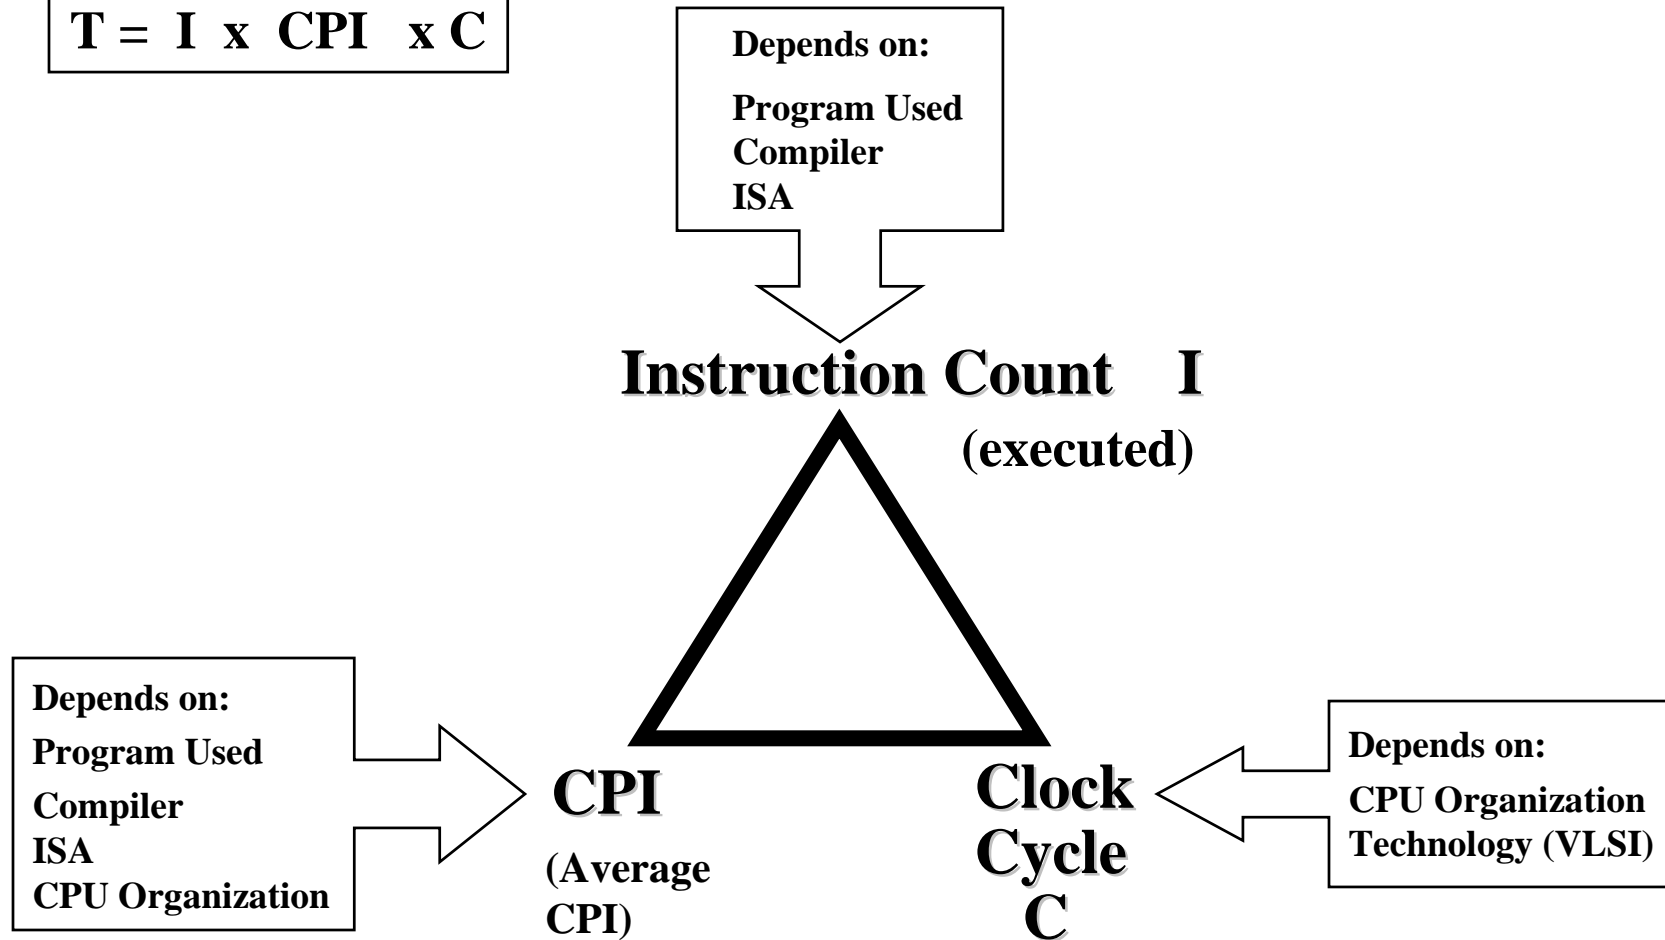

$$T = I \times \text{CPI} \times C$$

EECC550 - Shaaban

Aspects of CPU Execution Time

CPU Time = Instruction count executed x CPI x Clock cycle

$$T = I \times \text{CPI} \times C$$

EECC550 - Shaaban

Performance Comparison: Example

- From the previous example: A Program is running on a specific machine (CPU) with the following parameters:
 - Total executed instruction count, I: 10,000,000 instructions
 - Average CPI for the program: 2.5 cycles/instruction.
 - CPU clock rate: 200 MHz. Thus: $C = 1/(200 \times 10^6) = 5 \times 10^{-9}$ seconds
- Using the same program with these changes:
 - A new compiler used: New executed instruction count, I: 9,500,000
New CPI: 3.0
 - Faster CPU implementation: New clock rate = 300 MHz Thus: $C = 1/(300 \times 10^6) = 3.33 \times 10^{-9}$ seconds
- What is the speedup with the changes?

$$\text{Speedup} = \frac{\text{Old Execution Time}}{\text{New Execution Time}} = \frac{I_{\text{old}} \times \text{CPI}_{\text{old}} \times \text{Clock cycle}_{\text{old}}}{I_{\text{new}} \times \text{CPI}_{\text{new}} \times \text{Clock Cycle}_{\text{new}}}$$

$$\begin{aligned} \text{Speedup} &= (10,000,000 \times 2.5 \times 5 \times 10^{-9}) / (9,500,000 \times 3 \times 3.33 \times 10^{-9}) \\ &= .125 / .095 = 1.32 \\ &\text{or } 32 \% \text{ faster after changes.} \end{aligned}$$

$$\text{Clock Cycle} = C = 1/ \text{Clock Rate}$$

$$T = I \times \text{CPI} \times C$$

EECC550 - Shaaban

Instruction Types & CPI

- Given a program with n types or classes of instructions executed on a given CPU with the following characteristics:

C_i = Count of instructions of type _{i} executed

CPI_i = Cycles per instruction for type _{i}

e.g ALU, Branch etc.

$i = 1, 2, \dots, n$

Depends on CPU Design

Then:

$$\text{CPI} = \text{CPU Clock Cycles} / \text{Instruction Count } I$$

i.e average or effective CPI

Executed

Where:

$$\text{CPU clock cycles} = \sum_{i=1}^n (CPI_i \times C_i)$$

$$\text{Executed Instruction Count } I = \sum C_i$$

$$T = I \times CPI \times C$$

EECC550 - Shaaban

Instruction Types & CPI: An Example

- An instruction set has three instruction classes:

Instruction class	CPI
A	1
B	2
C	3

e.g ALU, Branch etc. ———

For a specific CPU design

- Two code sequences have the following instruction counts:

Program	Instruction counts for instruction class		
Code Sequence	A	B	C
1	2	1	2
2	4	1	1

- CPU cycles for sequence 1 = $2 \times 1 + 1 \times 2 + 2 \times 3 = 10$ cycles

CPI for sequence 1 = clock cycles / instruction count

i.e average or effective CPI

$$= 10 / 5 = 2$$

- CPU cycles for sequence 2 = $4 \times 1 + 1 \times 2 + 1 \times 3 = 9$ cycles

CPI for sequence 2 = $9 / 6 = 1.5$

$$CPU \text{ clock cycles} = \sum_{i=1}^n (CPI_i \times C_i)$$

$$CPI = CPU \text{ Cycles} / I$$

EECC550 - Shaaban

Instruction Frequency & CPI

- Given a program with n types or classes of instructions with the following characteristics:

C_i = Count of instructions of type $_i$ executed

$i = 1, 2, \dots, n$

CPI_i = Average cycles per instruction of type $_i$

F_i = Frequency or fraction of instruction type $_i$ executed
= $C_i / \text{total executed instruction count} = C_i / I$

Then:

Where: Executed Instruction Count $I = \sum C_i$

$$CPI = \sum_{i=1}^n (CPI_i \times F_i)$$

i.e average or effective CPI

Fraction of total execution time for instructions of type $i = \frac{CPI_i \times F_i}{CPI}$

$$T = I \times CPI \times C$$

EECC550 - Shaaban

Instruction Type Frequency & CPI: A RISC Example

Program Profile or Executed Instructions Mix

Base Machine (Reg / Reg)

Depends on CPU Design

Op	Freq, F_i	CPI_i	$CPI_i \times F_i$	% Time
ALU	50%	1	.5	23% = $.5/2.2$
Load	20%	5	1.0	45% = $1/2.2$
Store	10%	3	.3	14% = $.3/2.2$
Branch	20%	2	.4	18% = $.4/2.2$

Given

Typical Mix

Sum = 2.2

$$CPI = \sum_{i=1}^n (CPI_i \times F_i)$$

i.e average or effective CPI

$$CPI = .5 \times 1 + .2 \times 5 + .1 \times 3 + .2 \times 2 = 2.2$$

$$= .5 + 1 + .3 + .4$$

$$T = I \times CPI \times C$$

EECC550 - Shaaban

Metrics of Computer Performance

(Measures)

Each metric has a purpose, and each can be misused.

Choosing Programs To Evaluate Performance

Levels of programs or benchmarks that could be used to evaluate performance:

- **Actual Target Workload:** Full applications that run on the target machine.
- **Real Full Program-based Benchmarks:**
 - Select a specific mix or suite of programs that are typical of targeted applications or workload (e.g SPEC95, SPEC CPU2000).
- **Small “Kernel” Benchmarks:** Also called synthetic benchmarks
 - Key computationally-intensive pieces extracted from real programs.
 - Examples: Matrix factorization, FFT, tree search, etc.
 - Best used to test specific aspects of the machine.
- **Microbenchmarks:**
 - Small, specially written programs to isolate a specific aspect of performance characteristics: Processing: integer, floating point, local memory, input/output, etc.

Types of Benchmarks

Pros

- Representative

Actual Target Workload

- Portable.
- Widely used.
- Measurements useful in reality.

Full Application Benchmarks

- Easy to run, early in the design cycle.

Small “Kernel” Benchmarks

- Identify peak performance and potential bottlenecks.

Microbenchmarks

Cons

- Very specific.
- Non-portable.
- Complex: Difficult to run, or measure.

- Less representative than actual workload.

- Easy to “fool” by designing hardware to run them well.

- Peak performance results may be a long way from real application performance

EECC550 - Shaaban

SPEC: System Performance Evaluation Corporation

The most popular and industry-standard set of CPU benchmarks.

Programs application domain: Engineering and scientific computation

- **SPECmarks, 1989:**

- 10 programs yielding a single number (“SPECmarks”).

- **SPEC92, 1992:**

- SPECInt92 (6 integer programs) and SPECfp92 (14 floating point programs).

- **SPEC95, 1995:**

- SPECInt95 (8 integer programs):
 - go, m88ksim, gcc, compress, li, ijpeg, perl, vortex
- SPECfp95 (10 floating-point intensive programs):
 - tomcatv, swim, su2cor, hydro2d, mgrid, applu, turb3d, apsi, fppp, wave5
- Performance relative to a Sun SuperSpark I (50 MHz) which is given a score of SPECInt95 = SPECfp95 = 1

- **SPEC CPU2000, 1999:**

- CINT2000 (11 integer programs). CFP2000 (14 floating-point intensive programs)
- Performance relative to a Sun Ultra5_10 (300 MHz) which is given a score of SPECInt2000 = SPECfp2000 = 100

- **SPEC CPU2006, 2006:**

- CINT2006 (12 integer programs). CFP2006 (17 floating-point intensive programs)
- Performance relative to a Sun Ultra Enterprise 2 workstation with a 296-MHz UltraSPARC II processor which is given a score of SPECInt2006 = SPECfp2006 = 1

All based on execution time and give speedup over a reference CPU

EECC550 - Shaaban

SPEC95 Programs

Programs application domain: Engineering and scientific computation

	Benchmark	Description
Integer	go	Artificial intelligence; plays the game of Go
	m88ksim	Motorola 88k chip simulator; runs test program
	gcc	The Gnu C compiler generating SPARC code
	compress	Compresses and decompresses file in memory
	li	Lisp interpreter
	jpeg	Graphic compression and decompression
	perl	Manipulates strings and prime numbers in the special-purpose programming language Perl
	vortex	A database program
Floating Point	tomcatv	A mesh generation program
	swim	Shallow water model with 513 x 513 grid
	su2cor	quantum physics; Monte Carlo simulation
	hydro2d	Astrophysics; Hydrodynamic Navier Stokes equations
	mgrid	Multigrid solver in 3-D potential field
	applu	Parabolic/elliptic partial differential equations
	trub3d	Simulates isotropic, homogeneous turbulence in a cube
	apsi	Solves problems regarding temperature, wind velocity, and distribution of pollutant
	fpppp	Quantum chemistry
	wave5	Plasma physics; electromagnetic particle simulation

Resulting Performance relative to a Sun SuperSpark I (50 MHz) which is given a score of SPECint95 = SPECfp95 = 1

Performance relative to Base Processor a 296-MHz UltraSPARC II which is given a score of SPECint2006 = SPECfp2006 = 1

T on base processor

EECC550 - Shaaban

Computer Performance Measures :

MIPS (Million Instructions Per Second) Rating

- For a specific program running on a specific CPU the MIPS rating is a measure of how many millions of instructions are executed per second:

$$\text{MIPS Rating} = \text{Instruction count} / (\text{Execution Time} \times 10^6)$$

$$= \text{Instruction count} / (\text{CPU clocks} \times \text{Cycle time} \times 10^6)$$

$$= (\text{Instruction count} \times \text{Clock rate}) / (\text{Instruction count} \times \text{CPI} \times 10^6)$$

$$= \text{Clock rate} / (\text{CPI} \times 10^6)$$

- Major problem with MIPS rating: As shown above the MIPS rating does not account for the count of instructions executed (I).
 - A higher MIPS rating in many cases may not mean higher performance or better execution time. i.e. due to compiler design variations.
- In addition the MIPS rating:
 - Does not account for the instruction set architecture (ISA) used.
 - Thus it cannot be used to compare computers/CPU's with different instruction sets.
 - Easy to abuse: Program used to get the MIPS rating is often omitted.
 - Often the Peak MIPS rating is provided for a given CPU which is obtained using a program comprised entirely of instructions with the lowest CPI for the given CPU design which does not represent real programs.

$$T = I \times \text{CPI} \times C$$

Computer Performance Measures :

MIPS (Million Instructions Per Second) Rating

- Under what conditions can the MIPS rating be used to compare performance of different CPUs?
- The MIPS rating is only valid to compare the performance of different CPUs provided that the following conditions are satisfied:
 - 1 The same program is used
(actually this applies to all performance metrics)
 - 2 The same ISA is used
 - 3 The same compiler is used

⇒ (Thus the resulting programs used to run on the CPUs and obtain the MIPS rating are identical at the machine code level including the same instruction count) (binary)

Compiler Variations, MIPS & Performance: An Example

- For a machine (CPU) with instruction classes:

Instruction class	CPI
A	1
B	2
C	3

e.g ALU, Branch etc. ———

————— For a specific CPU design

- For a given high-level language program, two compilers produced the following executed instruction counts:

	Instruction counts (in millions) for each instruction class		
Code from:	A	B	C
Compiler 1	5	1	1
Compiler 2	10	1	1

- The machine is assumed to run at a clock rate of 100 MHz.

Compiler Variations, MIPS & Performance: An Example (Continued)

$$\text{MIPS} = \text{Clock rate} / (\text{CPI} \times 10^6) = 100 \text{ MHz} / (\text{CPI} \times 10^6)$$

$$\text{CPI} = \text{CPU execution cycles} / \text{Instructions count}$$

$$\text{CPU clock cycles} = \sum_{i=1}^n (\text{CPI}_i \times C_i)$$

$$\text{CPU time} = \text{Instruction count} \times \text{CPI} / \text{Clock rate}$$

- For compiler 1:
 - $\text{CPI}_1 = (5 \times 1 + 1 \times 2 + 1 \times 3) / (5 + 1 + 1) = 10 / 7 = 1.43$
 - $\text{MIPS Rating}_1 = 100 / (1.428 \times 10^6) = 70.0 \text{ MIPS}$
 - $\text{CPU time}_1 = ((5 + 1 + 1) \times 10^6 \times 1.43) / (100 \times 10^6) = 0.10 \text{ seconds}$
- For compiler 2:
 - $\text{CPI}_2 = (10 \times 1 + 1 \times 2 + 1 \times 3) / (10 + 1 + 1) = 15 / 12 = 1.25$
 - $\text{MIPS Rating}_2 = 100 / (1.25 \times 10^6) = 80.0 \text{ MIPS}$
 - $\text{CPU time}_2 = ((10 + 1 + 1) \times 10^6 \times 1.25) / (100 \times 10^6) = 0.15 \text{ seconds}$

MIPS rating indicates that compiler 2 is better
while in reality the code produced by compiler 1 is faster

EECC550 - Shaaban

MIPS (The ISA not the metric) Loop Performance Example

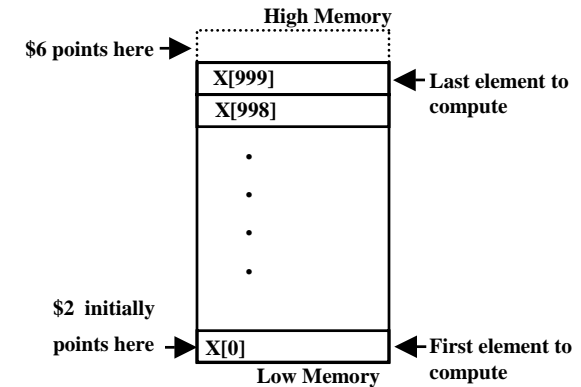

For the loop:

```
for (i=0; i<1000; i=i+1){
    x[i] = x[i] + s; }
```

MIPS assembly code is given by:

```

        lw     $3, 0($1)      ; load s in $3
        addi  $6, $2, 4000   ; $6 = address of last element + 4
loop:   lw     $4, 0($2)      ; load x[i] in $4
        add   $5, $4, $3     ; $5 has x[i] + s
        sw   $5, 0($2)      ; store computed x[i]
        addi  $2, $2, 4      ; increment $2 to point to next x[ ] element
        bne  $6, $2, loop    ; last loop iteration reached?
```

The MIPS code is executed on a specific CPU that runs at 500 MHz ($C = \text{clock cycle} = 2\text{ns} = 2 \times 10^{-9}$ seconds) with following instruction type CPIs :

Instruction type	CPI
ALU	4
Load	5
Store	7
Branch	3

For this MIPS code running on this CPU find:

- 1- Fraction of total instructions executed for each instruction type
- 2- Total number of CPU cycles
- 3- Average CPI
- 4- Fraction of total execution time for each instructions type
- 5- Execution time
- 6- MIPS rating , peak MIPS rating for this CPU

$X[]$ array of words in memory, base address in $\$2$,
 s a constant word value in memory, address in $\$1$

EECC550 - Shaaban

MIPS (The ISA) Loop Performance Example (continued)

- The code has 2 instructions before the loop and 5 instructions in the body of the loop which iterates 1000 times,
- Thus: Total instructions executed, $I = 5 \times 1000 + 2 = 5002$ instructions

1 Number of instructions executed/fraction F_i for each instruction type:

- ALU instructions = $1 + 2 \times 1000 = 2001$ $CPI_{ALU} = 4$ $Fraction_{ALU} = F_{ALU} = 2001/5002 = 0.4 = 40\%$
- Load instructions = $1 + 1 \times 1000 = 1001$ $CPI_{Load} = 5$ $Fraction_{Load} = F_{Load} = 1001/5002 = 0.2 = 20\%$
- Store instructions = 1000 $CPI_{Store} = 7$ $Fraction_{Store} = F_{Store} = 1000/5002 = 0.2 = 20\%$
- Branch instructions = 1000 $CPI_{Branch} = 3$ $Fraction_{Branch} = F_{Branch} = 1000/5002 = 0.2 = 20\%$

$$2 \text{ CPU clock cycles} = \sum_{i=1}^n (CPI_i \times C_i)$$

$$= 2001 \times 4 + 1001 \times 5 + 1000 \times 7 + 1000 \times 3 = 23009 \text{ cycles}$$

$$3 \text{ Average CPI} = \text{CPU clock cycles} / I = 23009/5002 = 4.6$$

4 Fraction of execution time for each instruction type:

- Fraction of time for ALU instructions = $CPI_{ALU} \times F_{ALU} / CPI = 4 \times 0.4 / 4.6 = 0.348 = 34.8\%$
- Fraction of time for load instructions = $CPI_{load} \times F_{load} / CPI = 5 \times 0.2 / 4.6 = 0.217 = 21.7\%$
- Fraction of time for store instructions = $CPI_{store} \times F_{store} / CPI = 7 \times 0.2 / 4.6 = 0.304 = 30.4\%$
- Fraction of time for branch instructions = $CPI_{branch} \times F_{branch} / CPI = 3 \times 0.2 / 4.6 = 0.13 = 13\%$

Instruction type	CPI
ALU	4
Load	5
Store	7
Branch	3

$$5 \text{ Execution time} = I \times CPI \times C = \text{CPU cycles} \times C = 23009 \times 2 \times 10^{-9} =$$

$$= 4.6 \times 10^{-5} \text{ seconds} = 0.046 \text{ msec} = 46 \text{ usec}$$

$$6 \text{ MIPS rating} = \text{Clock rate} / (CPI \times 10^6) = 500 / 4.6 = 108.7 \text{ MIPS}$$

- The CPU achieves its peak MIPS rating when executing a program that only has instructions of the type with the lowest CPI. In this case branches with $CPI_{Branch} = 3$
- Peak MIPS rating = $\text{Clock rate} / (CPI_{Branch} \times 10^6) = 500/3 = 166.67 \text{ MIPS}$

Computer Performance Measures :

MFLOPS (Million FLOating-Point Operations Per Second)

- A floating-point operation is an addition, subtraction, multiplication, or division operation applied to numbers represented by a single or a double precision floating-point representation.
- MFLOPS, for a specific program running on a specific computer, is a measure of millions of floating point-operation (megaflops) per second:

$$\text{MFLOPS} = \text{Number of floating-point operations} / (\text{Execution time} \times 10^6)$$

- MFLOPS rating is a better comparison measure between different machines (applies even if ISAs are different) than the MIPS rating.
 - Applicable even if ISAs are different
- Program-dependent: Different programs have different percentages of floating-point operations present. i.e compilers have no floating-point operations and yield a MFLOPS rating of zero.
- Dependent on the type of floating-point operations present in the program.
 - Peak MFLOPS rating for a CPU: Obtained using a program comprised entirely of the simplest floating point instructions (with the lowest CPI) for the given CPU design which does not represent real floating point programs.

Current peak MFLOPS rating: 8,000-20,000
MFLOPS (8-20 GFLOPS) per processor core

EECC550 - Shaaban

Quantitative Principles of Computer Design

- **Amdahl's Law:**

The performance gain from improving some portion of a computer is calculated by:

i.e using some enhancement

$$\text{Speedup} = \frac{\text{Performance for entire task using the enhancement}}{\text{Performance for the entire task without using the enhancement}}$$

or
$$\text{Speedup} = \frac{\text{Execution time without the enhancement}}{\text{Execution time for entire task using the enhancement}}$$

Before Enhancement

After Enhancement

Here: Task = Program

Recall: Performance = 1 / Execution Time

4th Edition: Chapter 1.8 3rd Edition: Chapter 4.5

EECC550 - Shaaban

Performance Enhancement Calculations: Amdahl's Law

- The performance enhancement possible due to a given design improvement is limited by the amount that the improved feature is used
- Amdahl's Law:

Performance improvement or speedup due to enhancement E:

$$\text{Speedup}(E) = \frac{\text{Execution Time without E}}{\text{Execution Time with E}} = \frac{\text{Performance with E}}{\text{Performance without E}}$$

original

- Suppose that enhancement E accelerates a fraction F of the execution time by a factor S and the remainder of the time is unaffected then:

$$\text{Execution Time with E} = ((1-F) + F/S) \times \text{Execution Time without E}$$

Hence speedup is given by:

$$\text{Speedup}(E) = \frac{\text{Execution Time without E}}{((1 - F) + F/S) \times \text{Execution Time without E}} = \frac{1}{(1 - F) + F/S}$$

F (Fraction of execution time enhanced) refers to original execution time before the enhancement is applied

EECC550 - Shaaban

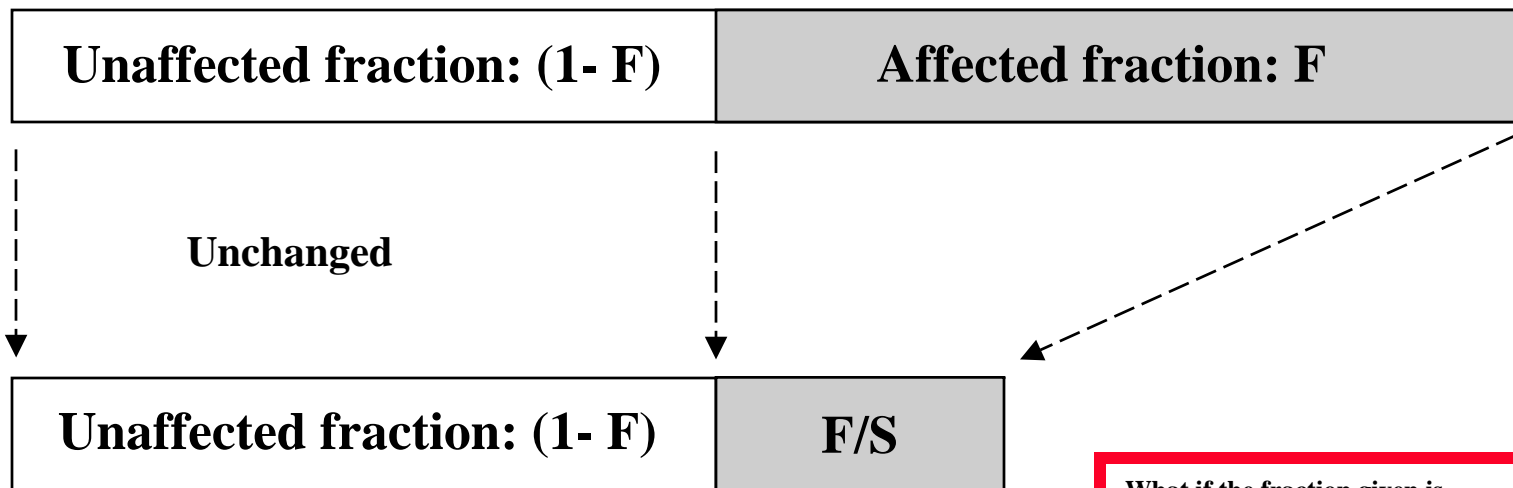

Pictorial Depiction of Amdahl's Law

Enhancement E accelerates fraction F of original execution time by a factor of S

Before:

Execution Time without enhancement E: (Before enhancement is applied)

- shown normalized to $1 = (1-F) + F = 1$

After:

Execution Time with enhancement E:

What if the fraction given is after the enhancement has been applied? How would you solve the problem? (i.e find expression for speedup)

$$\text{Speedup}(E) = \frac{\text{Execution Time without enhancement E}}{\text{Execution Time with enhancement E}} = \frac{1}{(1 - F) + F/S}$$

EECC550 - Shaaban

Performance Enhancement Example

- For the RISC machine with the following instruction mix given earlier:

Op	Freq	Cycles	CPI(i)	% Time
ALU	50%	1	.5	23%
Load	20%	5	1.0	45%
Store	10%	3	.3	14%
Branch	20%	2	.4	18%

CPI = 2.2

From a previous example

- If a CPU design enhancement improves the CPI of load instructions from 5 to 2, what is the resulting performance improvement from this enhancement:

Fraction enhanced = $F = 45\%$ or $.45$

Unaffected fraction = $1 - F = 100\% - 45\% = 55\%$ or $.55$

Factor of enhancement = $S = 5/2 = 2.5$

Using Amdahl's Law:

$$\text{Speedup}(E) = \frac{1}{(1 - F) + F/S} = \frac{1}{.55 + .45/2.5} = 1.37$$

An Alternative Solution Using CPU Equation

Op	Freq	Cycles	CPI(i)	% Time	
ALU	50%	1	.5	23%	CPI = 2.2
Load	20%	5	1.0	45%	
Store	10%	3	.3	14%	
Branch	20%	2	.4	18%	

- If a CPU design enhancement improves the CPI of load instructions from 5 to 2, what is the resulting performance improvement from this enhancement:

Old CPI = 2.2

New CPI of load is now 2 instead of 5

New CPI = $.5 \times 1 + .2 \times 2 + .1 \times 3 + .2 \times 2 = 1.6$

$$\text{Speedup}(E) = \frac{\text{Original Execution Time}}{\text{New Execution Time}} = \frac{\cancel{\text{Instruction count}} \times \text{old CPI} \times \cancel{\text{clock cycle}}}{\cancel{\text{Instruction count}} \times \text{new CPI} \times \cancel{\text{clock cycle}}}$$

$$= \frac{\text{old CPI}}{\text{new CPI}} = \frac{2.2}{1.6} = 1.37$$

Which is the same speedup obtained from Amdahl's Law in the first solution.

$$T = I \times \text{CPI} \times C$$

EECC550 - Shaaban

Performance Enhancement Example

- A program runs in 100 seconds on a machine with multiply operations responsible for 80 seconds of this time. By how much must the speed of multiplication be improved to make the program four times faster?

$$\text{Desired speedup} = 4 = \frac{100}{\text{Execution Time with enhancement}}$$

→ Execution time with enhancement = $100/4 = 25$ seconds

$$25 \text{ seconds} = (100 - 80 \text{ seconds}) + 80 \text{ seconds} / S$$

$$25 \text{ seconds} = 20 \text{ seconds} + 80 \text{ seconds} / S$$

→ $5 = 80 \text{ seconds} / S$

→ $S = 80/5 = 16$

Alternatively, it can also be solved by finding enhanced fraction of execution time:

$$F = 80/100 = .8$$

and then solving Amdahl's speedup equation for desired enhancement factor S

$$\text{Speedup}(E) = \frac{1}{(1 - F) + F/S} = 4 = \frac{1}{(1 - .8) + .8/S} = \frac{1}{.2 + .8/S}$$

Hence multiplication should be 16 times

Solving for S gives S= 16

faster to get an overall speedup of 4.

EECC550 - Shaaban

Performance Enhancement Example

- For the previous example with a program running in 100 seconds on a machine with multiply operations responsible for 80 seconds of this time. By how much must the speed of multiplication be improved to make the program five times faster?

$$\text{Desired speedup} = 5 = \frac{100}{\text{Execution Time with enhancement}}$$

$$\rightarrow \text{Execution time with enhancement} = 100/5 = 20 \text{ seconds}$$

$$20 \text{ seconds} = (100 - 80 \text{ seconds}) + 80 \text{ seconds} / s$$

$$20 \text{ seconds} = 20 \text{ seconds} + 80 \text{ seconds} / s$$

$$\rightarrow 0 = 80 \text{ seconds} / s$$

No amount of multiplication speed improvement can achieve this.

Extending Amdahl's Law To Multiple Enhancements

n enhancements each affecting a different portion of execution time

- Suppose that enhancement E_i accelerates a fraction F_i of the original execution time by a factor S_i and the remainder of the time is unaffected then:

$i = 1, 2, \dots, n$

$$\text{Speedup} = \frac{\text{Original Execution Time}}{\left((1 - \sum_i F_i) + \sum_i \frac{F_i}{S_i} \right) \times \text{Original Execution Time}}$$

Unaffected fraction \nearrow

$$\text{Speedup} = \frac{1}{\left((1 - \sum_i F_i) + \sum_i \frac{F_i}{S_i} \right)}$$

What if the fractions given are after the enhancements were applied? How would you solve the problem? (i.e find expression for speedup)

Note: All fractions F_i refer to original execution time before the enhancements are applied.

EECC550 - Shaaban

Amdahl's Law With Multiple Enhancements: Example

- Three CPU performance enhancements are proposed with the following speedups and percentage of the code original execution time affected:

$$\text{Speedup}_1 = S_1 = 10$$

$$\text{Percentage}_1 = F_1 = 20\%$$

$$\text{Speedup}_2 = S_2 = 15$$

$$\text{Percentage}_1 = F_2 = 15\%$$

$$\text{Speedup}_3 = S_3 = 30$$

$$\text{Percentage}_1 = F_3 = 10\%$$

- While all three enhancements are in place in the new design, each enhancement affects a different portion of the code and only one enhancement can be used at a time.
- What is the resulting overall speedup?

$$\text{Speedup} = \frac{1}{\left((1 - \sum_i F_i) + \sum_i \frac{F_i}{S_i} \right)}$$

- $$\begin{aligned} \text{Speedup} &= 1 / [(1 - .2 - .15 - .1) + .2/10 + .15/15 + .1/30] \\ &= 1 / [.55 + .0333] \\ &= 1 / .5833 = 1.71 \end{aligned}$$

Pictorial Depiction of Example

Before:

Execution Time with no enhancements: 1

i.e normalized to 1

After:

Execution Time with enhancements: $.55 + .02 + .01 + .00333 = .5833$

Speedup = $1 / .5833 = 1.71$

What if the fractions given are after the enhancements were applied? How would you solve the problem?

Note: All fractions F_i refer to original execution time.

“Reverse” Multiple Enhancements Amdahl's Law

- Multiple Enhancements Amdahl's Law assumes that the fractions given refer to original execution time.
- If for each enhancement S_i the fraction F_i it affects is given as a fraction of the resulting execution time after the enhancements were applied then:

$$Speedup = \frac{\left((1 - \sum_i F_i) + \sum_i F_i \times S_i \right) \times \text{Resulting Execution Time}}{\text{Resulting Execution Time}}$$

Unaffected fraction

$$Speedup = \frac{(1 - \sum_i F_i) + \sum_i F_i \times S_i}{1} = (1 - \sum_i F_i) + \sum_i F_i \times S_i$$

i.e as if resulting execution time is normalized to 1

- For the previous example assuming fractions given refer to resulting execution time after the enhancements were applied (not the original execution time), then:

$$\begin{aligned} Speedup &= (1 - .2 - .15 - .1) + .2 \times 10 + .15 \times 15 + .1 \times 30 \\ &= .55 + 2 + 2.25 + 3 \\ &= 7.8 \end{aligned}$$

Find original fractions?

EECC550 - Shaaban
